 - 3.1. Camera internal parameter calibration
 - 3.2. Start
 - 3.3. Program startup
 - 3.4 RANSAC Scheme
 - 3.5, Source code

1. Overview

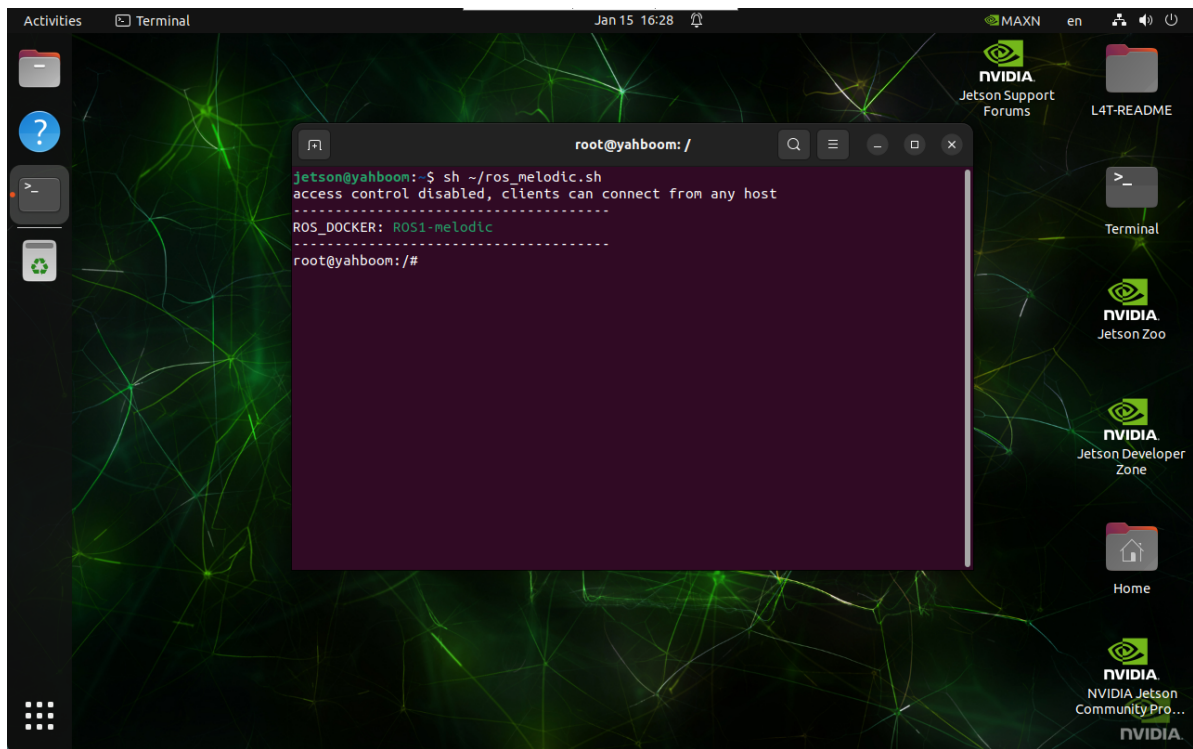

Augmented Reality, referred to as "AR", is a technology that cleverly integrates virtual information with the real world. It widely uses multimedia, three-dimensional modeling, real-time tracking and registration, intelligent interaction, sensing and other technical means to simulate computer-generated text, images, three-dimensional models, music, video and other virtual information and apply them to the real world. The two types of information complement each other, thereby achieving "enhancement" of the real world.

The AR system has three outstanding characteristics: ① Information integration of the real world and the virtual world; ② Real-time interactivity; ③ Adding and positioning virtual objects in three-dimensional space.

Augmented reality technology includes new technologies and new means such as multimedia, three-dimensional modeling, real-time video display and control, multi-sensor fusion, real-time tracking and registration, and scene fusion.

2. Enter Docker

```
sh ~/ros_melodic.sh
```

3. Usage

When using AR cases, the camera's internal parameters are required, otherwise it will not work (the factory image has completed the camera internal parameter calibration). The internal parameter file is in the same directory as the code.

3.1. Camera internal parameter calibration

Start the monocular camera

```
roslaunch usb_cam usb_cam-test.launch
```

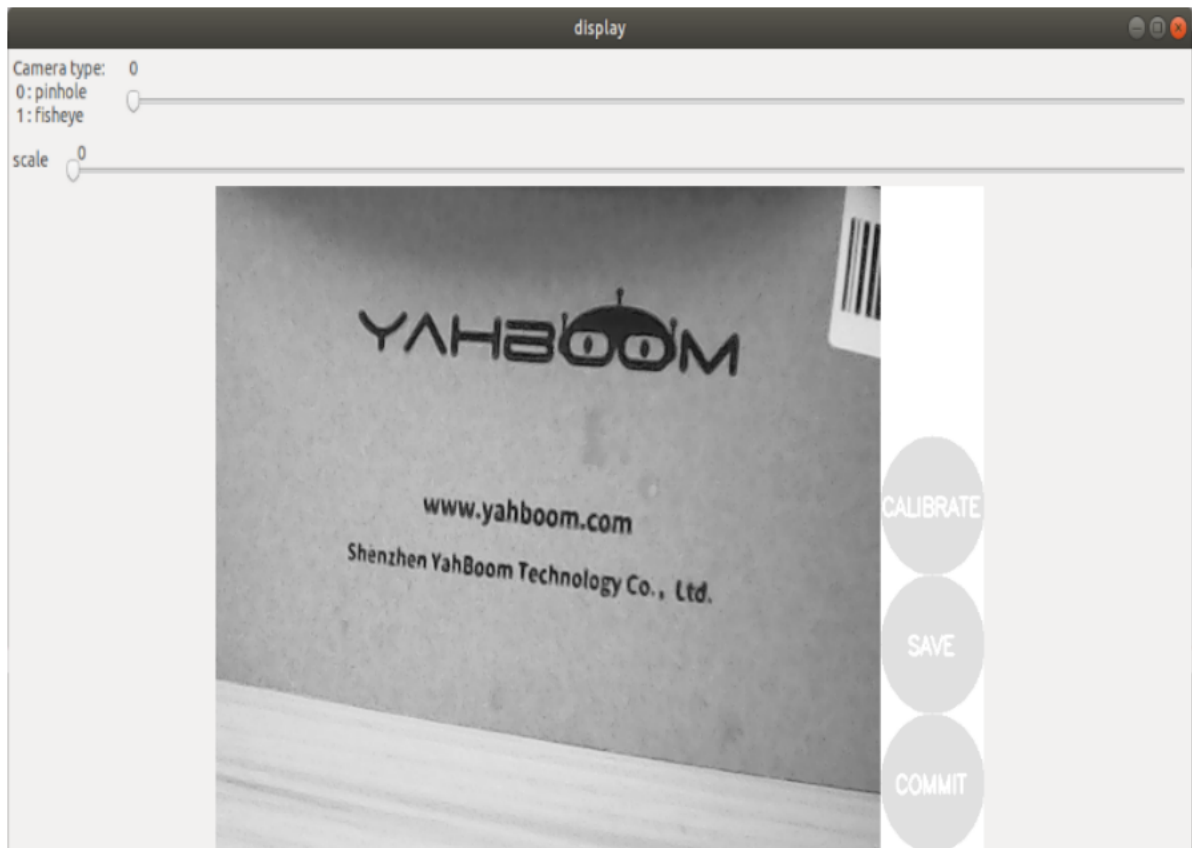

Start the calibration node

```
roslaunch camera_calibration cameracalibrator.py image:=/usb_cam/image_raw --size 9x6 --square 0.02
```

size: the number of internal corner points of the calibrated chessboard, for example, 9X6, the corner points have six rows and nine columns.

square: the side length of the chessboard, in meters.

image: the image topic published by the camera

Calibration interface

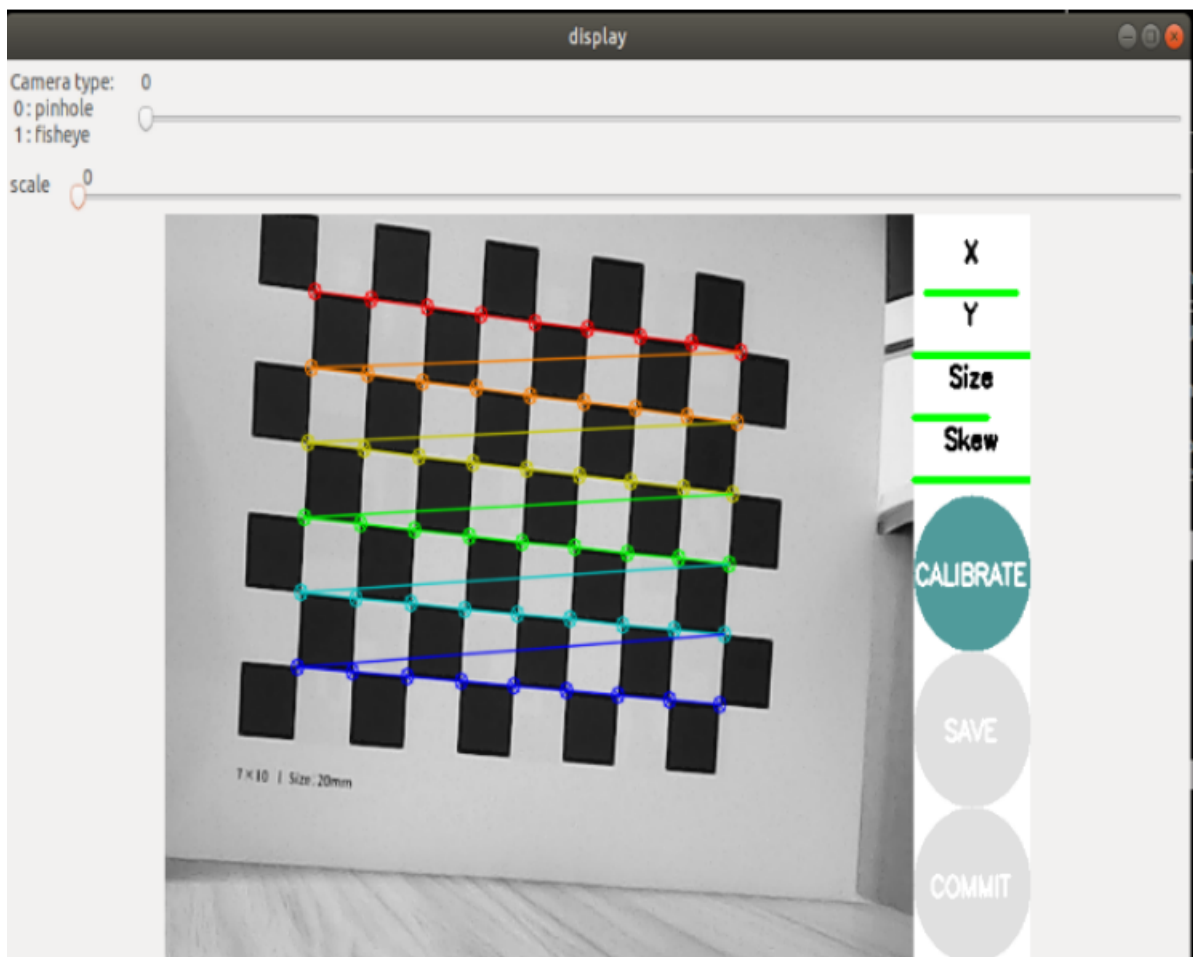

X: The chessboard moves left and right in the camera's field of view

Y: The chessboard moves up and down in the camera's field of view

Size: The chessboard moves forward and backward in the camera's field of view

Skew: The chessboard tilts and rotates in the camera's field of view

After successful startup, put the chessboard in the center of the screen and change different positions. The system will recognize it autonomously. The best situation is that the lines under [X], [Y], [Size], and [Skew] change from red to yellow and then to green as data is collected, and fill as much as possible.

- Click [CALIBRATE] to calculate the camera's internal parameters. The more pictures you have, the longer it will take. Just wait. (Sixty or seventy pictures is enough. Too many will cause the camera to freeze.)
- Click [SAVE] to save the calibration results to [/tmp/calibrationdata.tar.gz] of the current running terminal.

After the calibration is completed, you can move out the [/tmp/calibrationdata.tar.gz] file to view the contents.

```
sudo mv /tmp/calibrationdata.tar.gz ~
```

After decompression, there are the calibrated images, an ost.txt file and an ost.yaml file. ost.yaml is the internal reference for calibrating the camera. Copy the contents of the internal reference here and overwrite it to astra.yaml under /home/yahboom/dofbot_ws/src/dofbot_visual/AR.

3.2, Start

After the program is started, put the chessboard in front of the camera. Note that you need to see the entire chessboard, otherwise the program will exit. After the entire chessboard is recognized, the following 12 effects will be displayed,

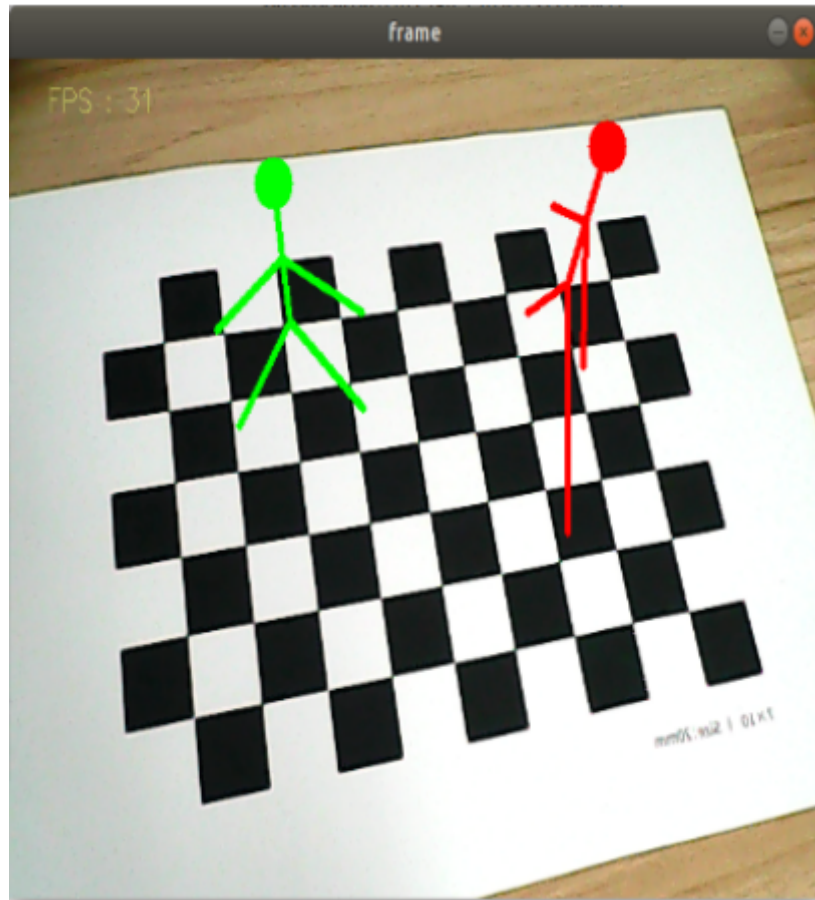

```
["Triangle", "Rectangle", "Parallelogram", "WindMill", "TableTennisTable",  
"Ball", "Arrow", "Knife", "Desk", "Bench", "Stickman", "ParallelBars"]
```

Click the image and press F to switch the displayed effect.

3.3. Program startup

Terminal input,

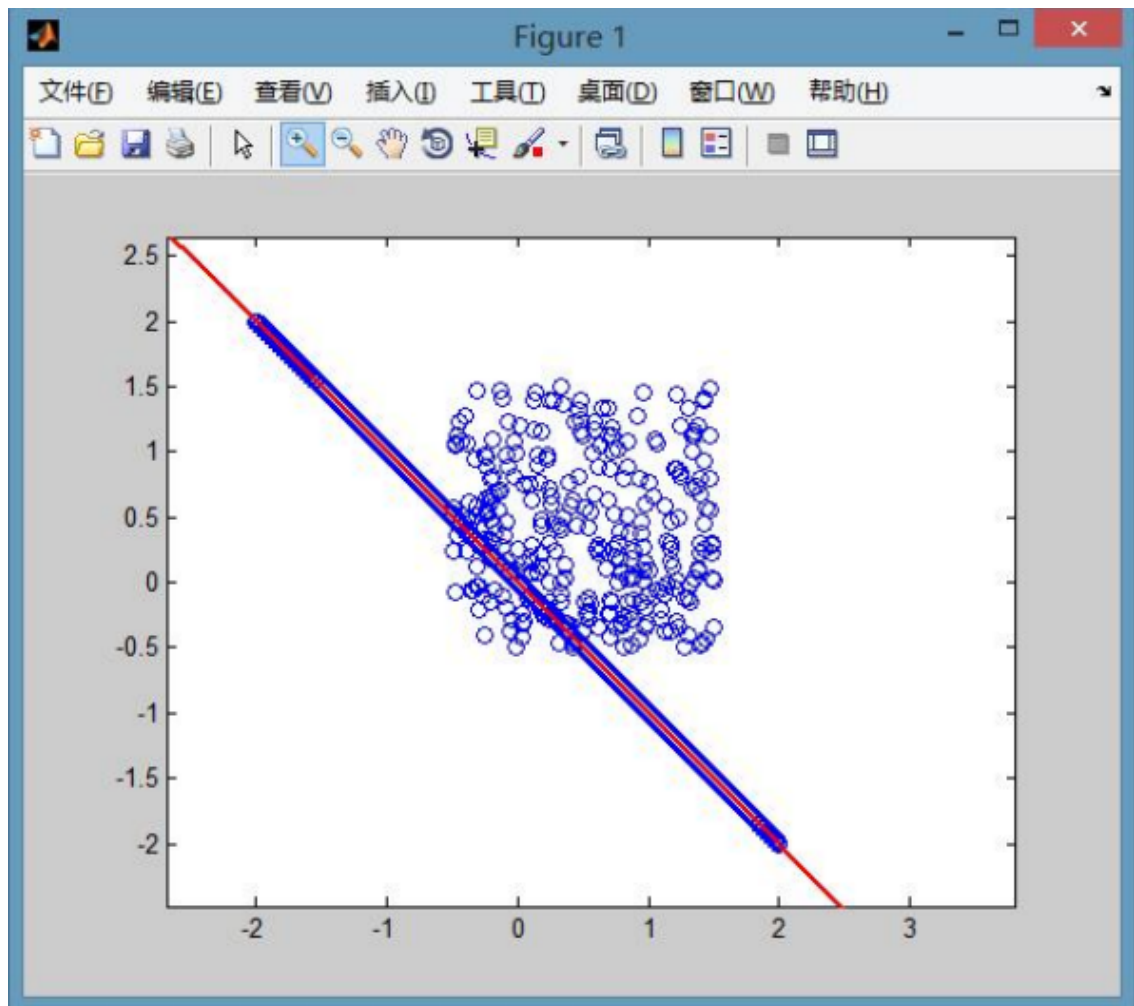

```
roscore  
roslaunch yahboomcar_visual simple_AR.py
```

3.4 RANSAC Scheme

- Algorithm principle: Use RANSAC scheme to find object pose from 3D-2D point correspondence

The Ransac algorithm (Random Sampling Consistency) was originally a classic algorithm for data processing. Its function is to extract specific components in an object under a large amount of noise. The following figure illustrates the effect of the Ransac algorithm. In the figure, some points obviously satisfy a certain straight line, and another group of points is pure noise. The purpose is to find the equation of the straight line under a large amount of noise. At this time, the amount of noise data is 3 times that of the straight line.

If the least squares method is used, this effect cannot be achieved and the straight line will be slightly above the straight line in the figure.

- The basic assumptions of RANSAC are:
 - The data consists of "in-game points", i.e., the distribution of the data can be explained by some model parameters;
 - "Outliers" are data that cannot be fitted into the model;
 - Any data other than this is noise.
- Outliers are caused by: extreme values of noise; incorrect measurement methods; incorrect assumptions about the data. RANSAC also makes the following assumptions: given a set of (usually small) inliers, there is a process that can estimate the model parameters; and the model can explain or apply to the inliers.
